

## FEATURES

- Identification of large signal model in real time
- Electrical and mechanical state variables (displacement, temperature, ...)
- For woofers in free air, sealed and vented enclosures
- For micro-speakers, headphones, mini-loudspeakers, tweeters, shakers
- Measures signal distortion on-line
- Full thermal and mechanical driver protection
- Finds dominant sources of distortion
- Locates weak points in design and assembly

## DESCRIPTION

The module LSI3 identifies the elements of the lumped parameter model of woofers, micro-speakers, headphones, tweeters, shakers, mini-loudspeakers and other electro-dynamical transducers. It allows to measure transducers mounted in an enclosure or in free air. The transducer is operated under normal working conditions and excited with a broadband noise signal. Starting in the small-signal domain the amplitude is gradually increased up to limits admissible for the particular transducer. The maximal amplitude is determined automatically using the identified transducer parameters and general protection parameters describing the thermal and mechanical load.

The identification of the model parameters is performed in real time using an adaptive system. It is based on the estimation of the back EMF from the voltage  $U(t)$  and current signal  $I(t)$  measured at the electrical terminals. The identified model allows locating the sources of the nonlinear distortion and their contribution to the radiated sound. The dynamic generation of a DC-part in the displacement, amplitude compression and other nonlinear effects can be investigated in detail.

1 Overview

1.1 Principle

The transducers considered here have a moving-coil assembly performing an electro-dynamical conversion of the electrical quantities (current and voltage) into mechanical quantities (velocity and force) and vice versa.

Equivalent Circuit

The lumped-parameter model shown above is used to describe the large signal behavior of electro-dynamical drivers at high amplitudes. In contrast to the well-known linear model the elements

- electro-dynamical force factor  $BI(x)$ ,
- compliance of mechanical suspension  $C_{ms}(x)$ ,
- voice coil inductance represented by  $L_e(x,i)$ ,  $L_2(x,i_2)$  and  $R_2(x,i_2)$ ,
- mechanical losses  $R_{ms}(v)$
- resistance of the voice coil at DC represented by  $R_e(T_v)$

are not constant parameters but depend on one or more speaker states (displacement  $x$ , input current  $i$ , voice coil temperature  $T_v$ ).

The additional impedance  $Z_{load}$  represents any additional mechanical or acoustical resonance caused by vented enclosure, panel, and horn. For a driver operated in free air the lumped parameter model assumes the impedance  $Z_{load}$  to be 0.

For the vented box system the mechanical load  $Z_{load}$  can be represented by the following equivalent circuit.

For the sealed-box system the mechanical load  $Z_{load}$  can be represented by the following equivalent circuit.

using acoustical compliance  $C_{ab}$

$$C_{ab} = \frac{V_0}{\rho_0 c_0^2}$$

representing the compression of the air volume  $V_0$  with air density  $\rho_0$  and speed of sound  $c_0$ . The Helmholtz resonance and Q factor are defined by

$$f_b = \frac{1}{2\pi} \frac{1}{\sqrt{M_{ap} C_{ab}}} \quad Q_b = \frac{1}{2\pi f_b C_{ab} R_{al}}$$

using mechanical compliance  $C_{mb}$

$$\frac{x}{F_{load}} = C_{mb} = \frac{1}{K_{mb}} = \frac{C_{ab}}{S_d^2} = \frac{V_0}{\rho_0 c_0^2 S_d^2}$$

which can be expressed by air volume  $V_0$ , air density  $\rho_0$  and speed of sound  $c_0$ .

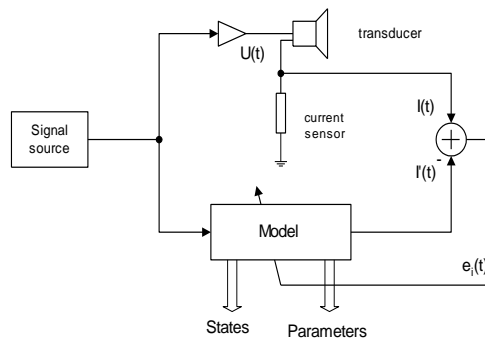

A total stiffness  $K_{mt}(x) = K_{ms}(x) + K_{mb}$  can be calculated.

Operation Condition

During the Large Signal Identification the transducer has to be operated in free air, in a sealed or in a vented enclosure. It is not recommended to attach an additional mass to the moving assembly because this mass might fall off at higher displacements.

### 1.2 Identification Technique

**Principle**

The transducer model is implemented as an adaptive system in a digital signal processor (DSP). The transducer is persistently excited by a broadband noise or multi-tone signal generated by a signal source via a power amplifier. The model which is excited with the voltage  $U(t)$  estimates the voice coil current  $I'(t)$  which is then compared with the measured current  $I(t)$ . The amplitude of the difference signal (error) is minimized by adjusting the model parameters adaptively. The output parameters are the optimal parameter estimates, the instantaneous state variables (displacement) and statistical values (RMS or peak value, crest factor) which may be investigated. There are two different LSI modules:

• LSI3 Woofer  
 • LSI3 Micro-speaker  
 which are defined below.

**LSI3 Woofer**

The LSI3 Woofer allows to measure woofers and other electro-dynamical transducers operated in free-air or coupled with an additional mechanical or acoustical resonator (vented enclosure, horn, panel) giving a total mechanical-acoustical system of 2<sup>nd</sup> or 4<sup>th</sup>-order.

There are three working modes:

- Free air:  
 Dedicated for woofers operated in free air. It assumes that the impedance  $Z_{load}=0$ .
- Sealed enclosure:  
 The stiffness  $K_{ms}(x)$  of the mechanical suspension is calculated from the total stiffness  $K_{mt}(x)$ .  $K_{mt}(x)$  is the sum of the mechanical stiffness  $K_{ms}(x)$  and the equivalent stiffness  $K_{mb}$  of the enclosed air in the enclosure which is calculated by using the air volume  $V_b$  and radiation area  $S_d$  of the cone provided by the user.
- Vented enclosure:  
 For a vented enclosure the mechanical stiffness  $K_{ms}(x)$  of the driver can be separated by considering the imported air volume  $V_b$  and radiation area  $S_d$ . The port resonance frequency  $f_b$  and  $Q_b$  factor is determined. This mode may be also used for measuring drive units coupled to an unknown additional resonator (e.g. first break-up mode on a panel) which is assumed to be linear.

**LSI3 Micro-speaker**

This module is dedicated for micro-speakers, tweeters, and horn compression drivers and which may be modeled by a 2<sup>nd</sup>-order mechanical system with a resonance frequency between 100 Hz and 1.5 kHz.

**Import Parameter**

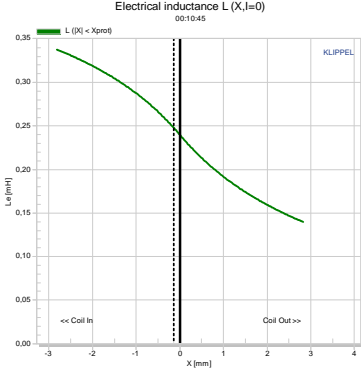

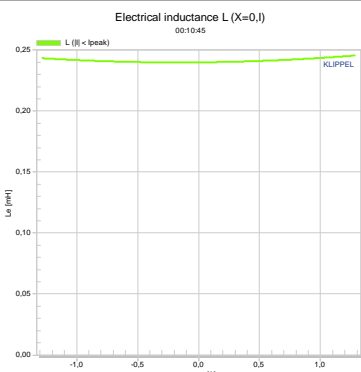

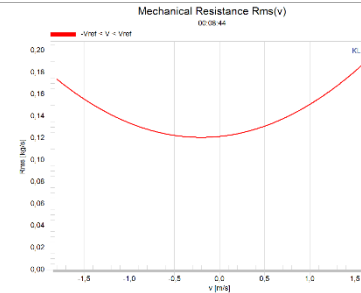

The minimal setup measures the electrical impedance at the transducer terminals and identifies the electrical system in absolute quantities whereas the mechanical system is identified in relative quantities only. Importing one mechanical parameter (moving mass  $M_{ms}$  or  $B/(x=0)$  at the rest position) allows to calibrate all state variables (e.g. the displacement in mm) and all of the mechanical parameters (e.g. compliance in mm/N).

<p><b>Laser</b></p>		<p>A laser sensor based on triangulation principle (see <i>A2 Laser Displacement Sensor</i>) can be used for measuring the voice coil displacement during the test. This information is used to calibrate the mechanical parameters in absolute terms.</p>
<p><b>Adaption</b></p>	<p>The estimation of the linear and nonlinear parameters consists of a series of steps processed sequentially:</p> <ul style="list-style-type: none"> <li>• Amplifier check (cables, gain control, limiting)</li> <li>• Measurement of resistance <math>R_e</math> at DC</li> <li>• Identification of the linear lumped parameters valid in the small signal domain</li> <li>• Identification of the admissible amplitude and the nonlinear parameters describing the transducer over its whole working range</li> </ul>	
<p><b>Acoustical Environment</b></p>	<p>The influence of the room acoustics on the driver parameters may be neglected having a normal room size (volume &gt; 30 m<sup>3</sup>) and keeping a distance of about 1 m to the walls.</p>	

**1.3 Results**

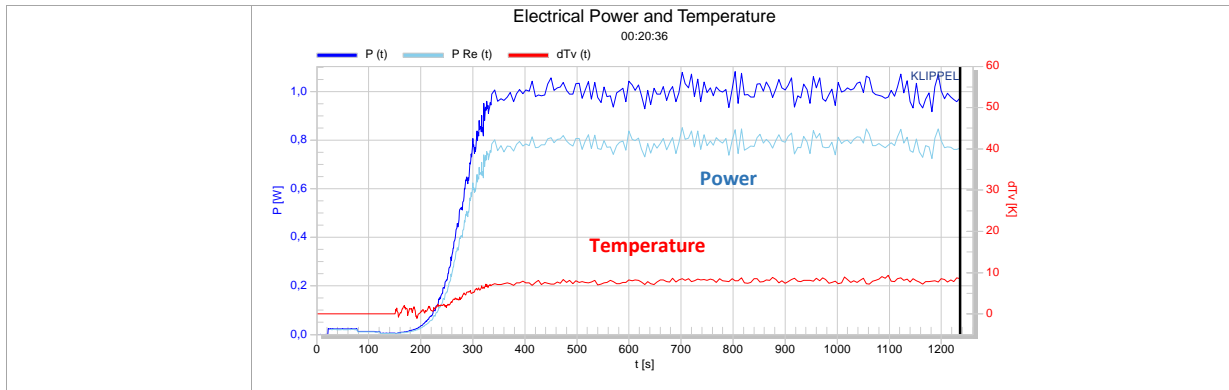

**TRANSDUCER NONLINEARITIES**

<p><b>Force Factor (BI-product)</b></p>		<p>The force factor <math>BI(x)</math> describes the integral of the induction <math>B</math> versus wire length <math>l</math> depending on the instantaneous coil position <math>x</math> in the gap. The <math>BI(x)</math> curve comprises a symmetrical and an asymmetrical component and decreases at high displacements. The asymmetry may be caused by the field geometry or by an offset of the coil. Variation of <math>BI(x)</math> versus <math>x</math> affects the parametric excitation of the driver (varying driving force) and the electrical damping at the resonance (loss factor <math>Q_{es}</math> is not constant).</p>
<p><b>Stiffness of Mechanical Suspension</b></p>		<p>The stiffness <math>K_{ms}(x)</math> which is the inverse of the compliance <math>C_{ms}(x)</math> describes the ratio of the instantaneous force and displacement at the working point <math>x</math>. A steep increase of the stiffness indicates the limit of the moving capability of the mechanical suspension. A variation of <math>K_{ms}(x)</math> corresponds with an instantaneous variation of the resonance frequency <math>f_s(x)</math> and the mechanical loss factor <math>Q_{ms}(x)</math> versus displacement.</p>

<p><b>Voice Coil Inductance versus displacement<sup>1</sup></b></p>		<p>The parameters representing the voice coil inductance <math>L_e(x)</math>, <math>L_2(x)</math> and <math>R_2(x)</math> are assumed to have the same nonlinear characteristic. Transducers not comprising components for reducing the inductance such as shorting rings or a pole cap have an asymmetrical shape. In this case the inductance increases when the voice coil is moved towards the back plate. Variation of the inductance parameters will affect the electrical impedance and produces a reluctance force on the mechanical side which may be interpreted as an additional electromagnetic driving mechanism.</p>
<p><b>Voice Coil Inductance versus current<sup>1</sup></b></p>		<p>The nonlinear <math>B(H)</math> characteristic of the iron causes a variation of the inductance <math>L(i)</math> versus voice coil current <math>i</math>. This nonlinearity is also called flux modulation or better permeability modulation. A symmetric characteristic shows a saturation of the iron at high positive and negative current. The curve becomes asymmetric for a high DC flux generated by the magnet. The parameter <math>L(i)</math> causes harmonic distortion at higher frequencies which can easily be detected in the input current.</p>
<p><b>Mechanical Resistance versus velocity<sup>2</sup></b></p>		<p>The dependency of the mechanical resistance <math>R_{ms}</math> on voice coil velocity <math>v</math> is a dominant nonlinearity in micro-speakers and other transducers which have a relatively high resonance frequency <math>f_s</math>, a relatively small force factor <math>Bl</math> and a total quality factor <math>Q_{ts}</math> dominated by the mechanical losses. The <math>R_{ms}(v)</math> nonlinearity causes a significant increase of the mechanical damping at resonance frequency, causing a nonlinear amplitude compression of the fundamental and generating significant harmonic and intermodulation distortion. There are strong indications that the nonlinear variation of <math>R_{ms}(v)</math> nonlinearity is not caused by the mechanical vibration of the diaphragm or other mechanical elements because this nonlinearity vanishes when the transducer is operated in vacuum.</p>
<p><b>TEMPORAL VARIATIONS OF STATES AND PARAMETERS</b></p>		
<p><b>Permanent Monitoring</b></p>	<p>During the identification process all of the parameter estimates and important characteristics of the state variables (peak and RMS values) are sampled periodically (about 2 –10 s) and recorded by the Klippel Analyzer. The complete recorded history can be analyzed to investigate temporal variations of the parameters due to thermal, reversible and irreversible processes.</p>	
<p><b>Temperature, Power</b></p>	<p>The voice coil temperature, the real input power <math>P_{real}</math> and the power <math>P_{Re}</math> dissipated on resistance <math>R_e</math> is permanently measured and recorded. This information is helpful to protect the driver against overload but is also used to identify the thermal parameters.</p>	

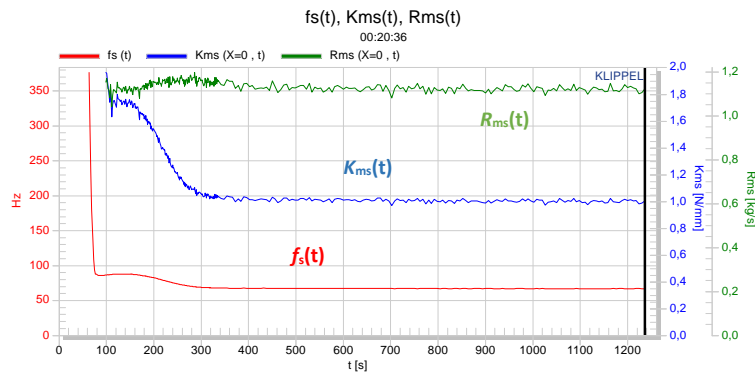

<sup>1</sup> LSI3 Woofer only

<sup>2</sup> LSI3 Microspeaker only

**Stiffness of Mechanical Suspension**

The properties of the mechanical suspension vary with time due to reversible and non-reversible processes (creep, ageing).

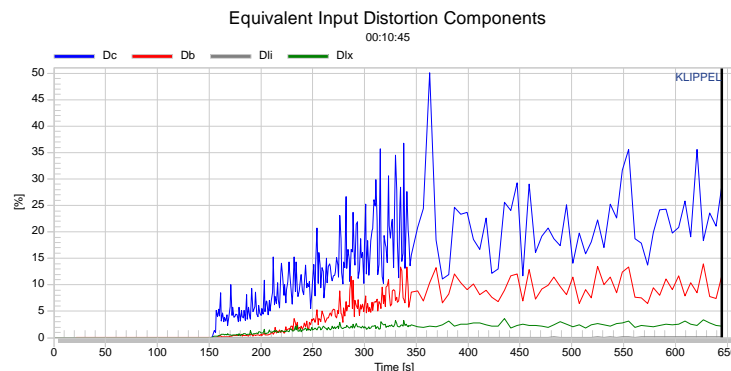

**Distortion Analysis**

The transducer may be modeled as a superposition of a linear system excited by the input signal  $u$  and the outputs of non-linear subsystems corresponding to the driver nonlinearities  $B_l(x)$ ,  $C_{ms}(s)$ ,  $L_e(x)$  and  $L_e(i)$ .

The implemented digital model makes it possible to measure the peak values of the outputs  $u_{C(x)}(t)$ ,  $u_{B_l(x)}(t)$ ,  $u_{L(i)}(t)$  and  $u_{L(x)}(t)$  of the nonlinear subsystems separately. These values are referred to the peak value of the total input signal  $u_{total}$ . The ratios are called instantaneous distortions  $d_C$ ,  $d_{B_l}$ ,  $d_L$  and  $d_{L(i)}$ , and show the contribution from each non-linearity versus measurement time.

This kind of distortion analysis shows the dominant source of distortion.

## 2 Requirements

### 2.1 Hardware

Product	Article	Spec
KA3 Klippel Analyzer 3	2000-300	H3
High Power Speaker Card (optional)		H8
Laser (optional)		A2

### 2.2 Software

Product	Article	Spec
dB-Lab (version 210.xx or higher)		F1
LSI3 Woofer (version 1.0 or higher)	2000-250	S52
LSI3 Micro-speaker (version 1.0 or higher)	2000-260	

## 3 Limitations

### 3.1 Device Under Test

Parameter	Symbol	Min	Typical	Max	Unit
Voice coil resistance					
Low Sensitivity - KA3 Current Sensor	$R_e$	0.5	2-8	100	$\Omega$
High Sensitivity - KA3 Current Sensor (For LSI3 Woofer & Micro-speaker)	$R_e$	1	4-30	1000	$\Omega$
Resonance frequency for					
LSI3 Woofer	$f_s$	15		400	Hz
LSI3 Micro-speaker	$f_s$	100		1500	Hz
Total loss factor	$Q_t$	0.3		6	
Voice-coil inductance	$L_e$	0.01		5	mH

### 3.2 Power Amplifier

Parameter	Symbol	Min	Typical	Max	Unit
Maximum input level				15	dBu
Frequency response Ref. 1kHz @ 5 Hz ... 20 kHz				1	dB
Input sensitivity at rated output power			0 (775)		dBu (mV)
Signal processing latency @ Woofer				9.5	ms
Signal processing latency @ Tweeter / Micro-speaker				3.5	ms

### 3.3 Input Parameters

Parameter	Symbol	Min	Typical	Max	Unit
<b>PROTECTION LIMITS</b>					
Small signal voltage	$U_{small}$	0.125	0.5	5	V
Small signal gain	$G_{small}$	-20		0	dB
Allowed increase of voice coil	$\Delta T_{lim}$	0	60	300	K

Parameter	Symbol	Min	Typical	Max	Unit
Allowed minimal value of the force factor ratio $Bl_{\min}$	$Bl_{\lim}$	25	50	100	%
Allowed minimal value of the mechanical compliance ratio $C_{\min}$	$C_{\lim}$	20	50	100	%
Allowed maximal value of electric input power P.	$P_{\lim}$	0.01		999	W
<b>STIMULUS</b>					
SIGNAL CHARACTERISTICS CAN BE ADJUSTED AUTOMATICALLY FOR THE DUT CONNECTED.					
Spectral Noise characteristic	pink or white noise (multi-tone for Micro-speaker)				
Cut-off frequency of high pass for Woofer (for Tweeter / Micro-speaker)	$f_{hp}$	10 (40)		150 (1200)	Hz
Cut-off frequency of low pass for Woofer (for Tweeter / Micro-speaker)	$f_{lp}$	200 (400)		1500 (4000)	Hz
<b>MATERIAL, IMPORTED PARAMETERS</b>					
Effective area of the driver diaphragm	$S_d$	> 0		10000	cm <sup>2</sup>
Material of voice coil	Copper, aluminum or custom temperature coefficient				
Temperature coefficient of voice coil material	alpha	0.001	0.0038	0.01	K <sup>-1</sup>
Force factor at rest position <sup>3</sup>	$Bl(x=0)$	> 0		100	N/A
Moving mass <sup>3</sup>	$M_{ms}$	0.001		10	kg
Box volume	$V_b$	> 0		1000	liter

## 4 Output

<b>PARAMETERS AT THE REST POSITION (X=0)</b>	
Electrical parameters $x \ll x_{max}$	$R_e, L_e, L_2, R_2, C_{ms}, L_{ces}, R_{es}$
Mechanical parameters $x \ll x_{max}$	$M_{ms}, R_{ms}, C_{ms}, Bl$
Derived parameters $x \ll x_{max}$	$Q_{ts}, Q_{ms}, Q_{es}, f_s$ $V_{as}, \eta_0, L_m$
Vented box parameters	$Q_b, f_b$
Temperature, power compression	$\Delta T_v, PC$
Predicted Impedance Magnitude	$Z(f)$
<b>STATES</b>	
Modeling and Measurement Errors	$E_i, E_x, E_u$
Nonlinear Parameter Variation	$Bl_{\min}, C_{\min}, L_{\min}$
Displacement	$x_{peak}, x_{bottom}, x_{dc}, x_{prot}$
Electrical signals	$u_{peak}, i_{peak}, u_{rms}, i_{rms}, P_{real}, P_{Re}$
Analyzed distortion components	$d_b, d_c, d_i, d_r$
<b>NONLINEAR PARAMETERS</b>	
Force factor ( $Bl$ -product)	$Bl(x), Bl(x_{rel}) / Bl(0)$
Suspension characteristic	$K_{ms}(x), C_{ms}(x), C_{ms}(x_{rel}) / C_{ms}(0)$
Displacement varying Inductance	$L_e(x), L_e(x_{rel})$
Current varying Inductance ("flux modulation")	$L_e(i)$
Mechanical losses	$R_{ms}(v)$

<sup>3</sup> absolute identification of the mechanical parameters without laser sensor requires import of  $Bl(x=0)$  or  $M_{ms}$

Coefficients of power series for $BI(x)$ , $C_{ms}(x)$ , $L(x)$	up to 8 <sup>th</sup> order
Derived parameters	$Q_{ts}(x, T_v)$ , $f_s(x)$
Displacement Limits	$x_{BI}(BI_{min})$ , $x_C(C_{min})$ , $x_L(Z_{max})$ , $x_d(d_2)$
Asymmetry	$x_{sym}$ , $a_{bl}$ , $a_{kms}$
Total Stiffness (suspension + air) in sealed enclosure	$K_{mt}(x)$
<b>THERMAL PARAMETERS</b>	
Thermal resistance	$R_{th}$
<b>HISTORY</b>	
Parameter and state variation versus measurement time $t$	
Background monitoring at high sample rate (Death Report)	
<b>EXPORT</b>	
Result windows to report generator	
Graphics to Clipboard, File (various formats)	
Parameters for Simulation
